Week 6

Exercise 45

../45/main.cc

```
1  #include <algorithm>
2  #include <iostream>
3  #include <iterator>
4  #include <set>
5  #include <string>
6
7  using namespace std;
8
9  int main(int argc, char const **argv)
10 {
11   set<string> iStrings;
12
13   cout << "Please enter delimited words to be sorted, end input with ^D \n";
14
15   copy(
16        istream_iterator<string>(cin),
17        istream_iterator<string>(),
18        inserter(iStrings,iStrings.end())
19       );
20
21   // Or: set<string> iStrings((istream_iterator<string>(cin)),
22   //                          istream_iterator<string>());
23
24   copy(
25        iStrings.begin(),
26        iStrings.end(),
27        ostream_iterator<string>(cout, " ")
28       );
29 }
```

Exercise 46

../46/main.cc

```
1  #include <vector>
2  #include <algorithm>
3  #include <iostream>
4  #include <string>
5
6  using namespace std;
7
8  int main(int argc, char **argv)
9  {
10   size_t nrRvalues = stoi(argv[1]);
11   size_t maxRvalue = stoi(argv[2]);
12   size_t lookupVal = stoi(argv[3]);
13
14   vector<size_t> numbers;
15
16   for (size_t idx = 0; idx < nrRvalues; ++idx)
17     numbers.push_back(random() % (maxRvalue + 1)); //adding a random number
18                                                    //between 0 and max_rvalue
19   for (auto idx: numbers)
20     cout << idx << '\t';
21   cout << '\n';
22
23   auto it = find_if(
24                       numbers.begin(),
25                       numbers.end(),
26                       [lookupVal](const size_t & val)
27                       {
28                         if (val > lookupVal)
29                           return true;
30                         return false;
31                       }
32                      );
33
34   if (it != numbers.end())
35     cout << "The first value exceeding " << lookupVal << " is at index "
36          << distance(numbers.begin(), it) << '\n';
37   else
38     cout << "No random value exceeds " << lookupVal << '\n';
39
40 }
```

Exercise 47

../47/main.cc

```cpp
#include <algorithm>
#include <iostream>
#include <iterator>

using namespace std;

int main(int argc, char **argv)
{
  sort(
       argv, argv + argc,
       [](char *left, char *right) // Sort ascending
       {
         return *left < *right;
       }
      );
  copy(argv, argv + argc, ostream_iterator<string>(cout, " ")); // Print

  cout << '\n'; // New line

  sort(
       argv,
       argv + argc,
       [](char *left, char *right) // Sort descending
       {
         return *left > *right;
       }
      );
  copy(argv, argv + argc, ostream_iterator<string>(cout, " ")); // Print
}
```

Exercise 48

The difference between `std::copy` and `std::for_each` is centered primarily around the fact that `std::copy` leaves the original intact (unless, of course, as in exercise 47 the destination range is the same as the origin). Furthermore, the `std::for_each` algorithm applies a 'transformation' (i.e. function) to the range, while copy does not. Hence, the latter is applicable for applications where some kind of function must be applied to all elements of a container.

../48/main.ih

```
#define ERR(msg) printf("%s : %d", (msg), __LINE__)

using namespace std;

#include <vector>
#include <algorithm>
#include <iterator>
#include <iostream>
```

../48/main.cc

```
#include "main.ih"

int main(int argc, char const **argv)
{
  vector<size_t> numbers {1, 2, 3, 4, 5, 6, 7};
  // Simple vector of ascending numbers

  copy(numbers.begin(), numbers.end(), ostream_iterator<size_t>(cout, "\n"));
  // Copies the vector to cout, printing them all, new-line seperated

  for_each(
           numbers.begin(),
           numbers.end(),
           [](size_t &n0)
           {
             cout << ++n0 << '\n';
           }
          );

  // The same, but now the numbers are incremented in the vector, as well as
  // printed
  // This could not be accomplished with copy
}
```

Exercise 49

../49E/main.ih

```
#define ERR(msg) printf("%s : %d", (msg), __LINE__)

using namespace std;

#include "student/student.h"

using namespace std;
```

../50–2/main.cc

```
#include "main.ih"

void operator>>(istream &istr, vector<string> &dest)
{
  std::copy(std::istream_iterator<Line>(istr), std::istream_iterator<Line>(),
   inserter(dest, dest.begin()));
}

int main(int argc, char **argv)
{
  vector<string> vs;

  cin >> vs;

  for (auto it: vs)
    cout << it << '\n';
}

/*
If we had used to use istream &operator>>(std::istream &istr, std::string &str)
rather than std::istream &operator>>(std::istream & is, Line &line)
(in line.h) then we would have extracted individual words rather than lines.
This is due to how istream_iterator<string> iterating works. It would use the
extraction operator to a string which is coded this way. By instead using
a istream_iterator<Line> we can create our own extraction operator which
returns lines instead of words.
*/
```

../50–2/line/line.h

```
